EECS 489 Computer Networks

Winter 2023

Z. Morley Mao

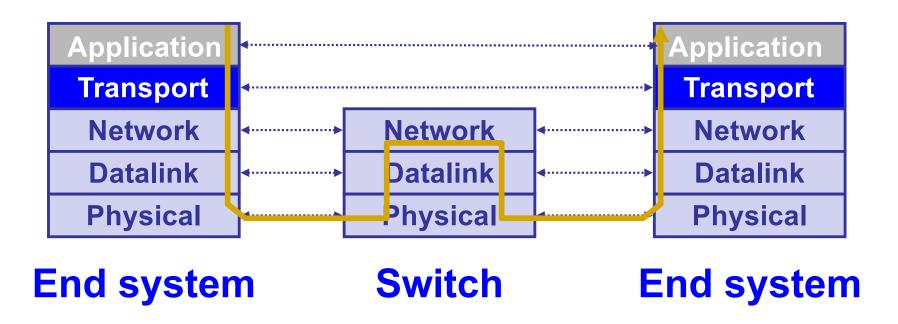

Material with thanks to Aditya Akella, Sugih Jamin, Philip Levis, Sylvia Ratnasamy, Peter Steenkiste, and many other colleagues.

Agenda

- Transport layer basics
- UDP
- Designing a reliable transport protocol

Transport layer

 Layer at end hosts, between the application and network layer

Why a transport layer?

- IP addresses capture hosts, but end-to-end communication happens between applications
 - Need a way to decide which packets go to which applications (multiplexing/demultiplexing)
- IP provides a weak service model (best-effort)
 - Packets can be corrupted, delayed, dropped, reordered, duplicated
 - No guidance on how much traffic to send and when
 - Dealing with this is tedious for application developers

Multiplexing & demultiplexing

Multiplexing (Mux)

Gather and combining data chunks at the source from different applications and delivering to the network layer

Demultiplexing (Demux)

Delivering correct data to corresponding sockets from a multiplexed stream

- Communication between processes
 - Mux and demux from/to application processes
 - Implemented using ports

- Communication between processes
- Provide common end-to-end services for app layer [optional]
 - Reliable, in-order data delivery
 - Well-paced data delivery
 - »Too fast may overwhelm the network
 - »Too slow is not efficient

- Communication between processes
- Provide common end-to-end services for app layer [optional]
- TCP and UDP are the common transport protocols
 - > Also SCTP, MPTCP, SST, RDP, DCCP, ...

- Communication between processes
- Provide common end-to-end services for app layer [optional]
- TCP and UDP are the common transport protocols
- UDP is a minimalist transport protocol
 - Only provides mux/demux capabilities

- Communication between processes
- Provide common end-to-end services for app layer [optional]
- TCP and UDP are the common transport protocols
- UDP is a minimalist transport protocol
- TCP offers a reliable, in-order, byte stream abstraction
 - With congestion control, but w/o performance guarantees (delay, b/w, etc.)

QUIC transport protocol

- The QUIC transport protocol (RFC 9000)
- Built on top of UDP
- QUIC packets are encrypted individually
- Faster connection setup by reusing the negotiated parameters from a previous connection
- Many other benefits: extensibility, reduced sensitivity to packet loss, reduced HoL, etc.

Applications and sockets

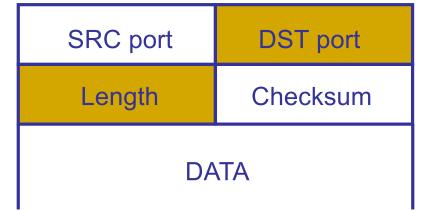

- Socket: software abstraction for an application process to exchange network messages with the (transport layer in the) operating system
- Two important types of sockets
 - UDP socket: TYPE is SOCK_DGRAM
 - TCP socket: TYPE is SOCK_STREAM

Ports

- 16-bit numbers that help distinguishing apps
 - Packets carry src/dst port no in transport header
 - Well-known (0-1023) and ephemeral ports
- OS stores mapping between sockets and ports
 - Port in packets and sockets in OS
 - For UDP ports (SOCK_DGRAM)
 - »OS stores (local port, local IP address) ←→ socket
 - For TCP ports (SOCK_STREAM)
 - »OS stores (local port, local IP, remote port, remote IP) ←→ socket

UDP: User Datagram Protocol

- Lightweight communication between processes
 - Avoid overhead and delays of order & reliability
- UDP described in RFC 768 (1980!)
 - Destination IP address and port to support demultiplexing

UDP (cont'd)

- Optional error checking on the packet contents
 - (checksum field = 0 means "don't verify checksum")
- Source port is also optional
 - Useful to respond back to the sender in some cases

Why a transport layer?

- IP packets are addressed to a host but end-toend communication is between application processes at hosts
 - Need a way to decide which packets go to which applications (mux/demux)
- IP provides a weak service model (best-effort)
 - Packets can be corrupted, delayed, dropped, reordered, duplicated
 - No guidance on how much traffic to send and when
 - Dealing with this is tedious for application developers

Reliable transport

In a perfect world, reliable transport is easy

@Sender

Send packets

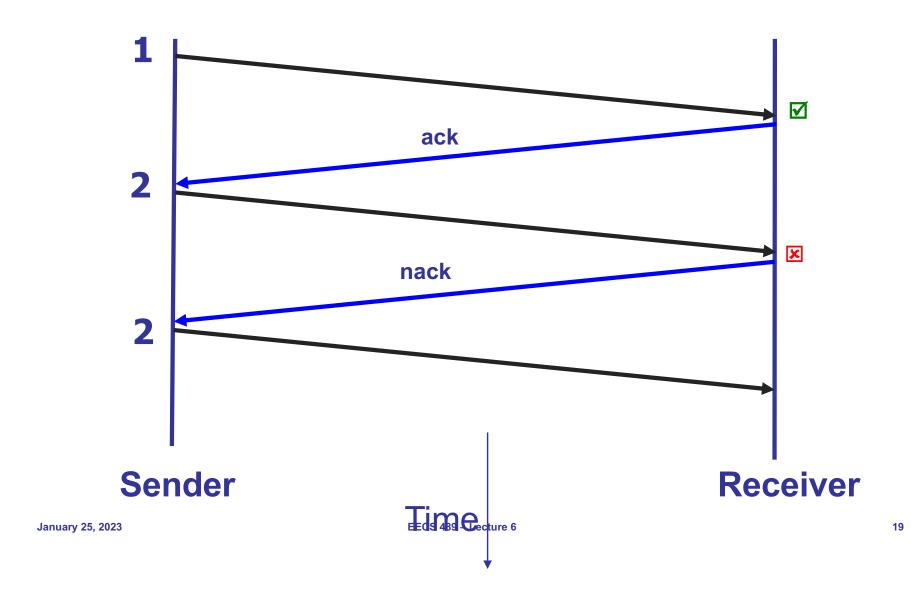

@Receiver

Wait for packets

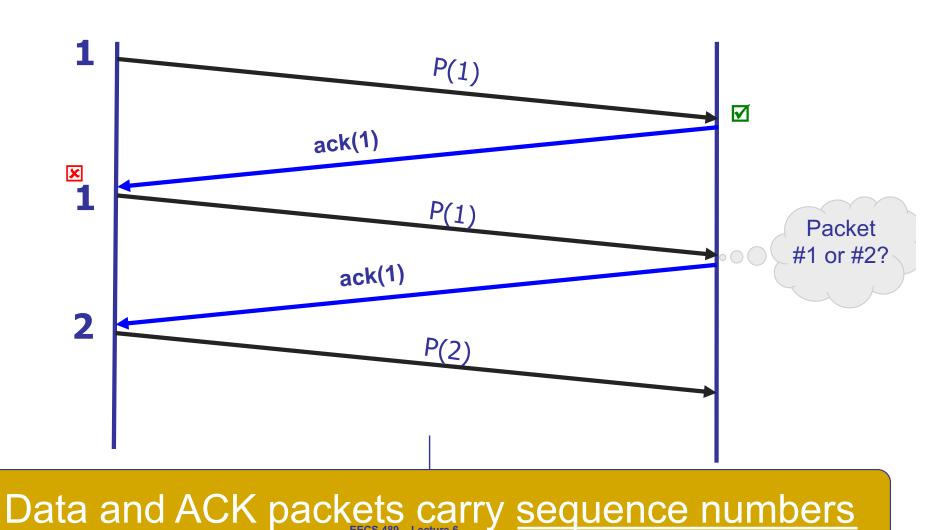

Reliable transport

- In a perfect world, reliable transport is easy
- All the bad things best-effort can do
 - A packet is corrupted (bit errors)
 - A packet is lost (why?)
 - A packet is delayed (why?)
 - Packets are reordered (why?)
 - A packet is duplicated (why?)

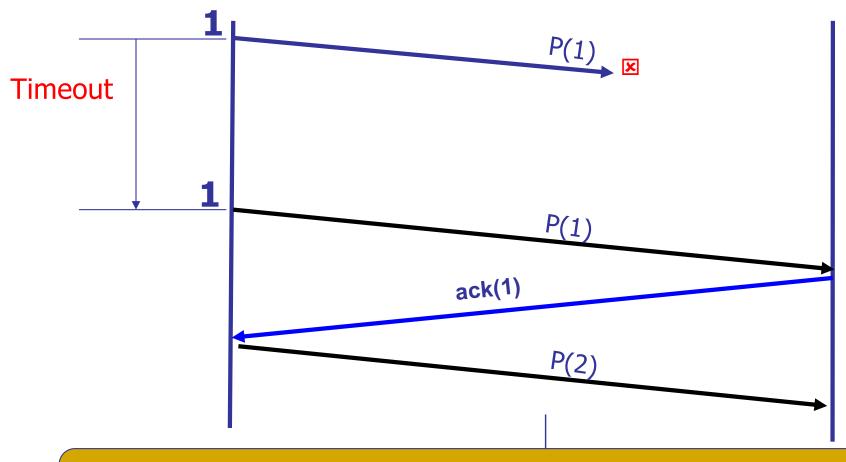

Dealing with packet corruption

Dealing with packet corruption

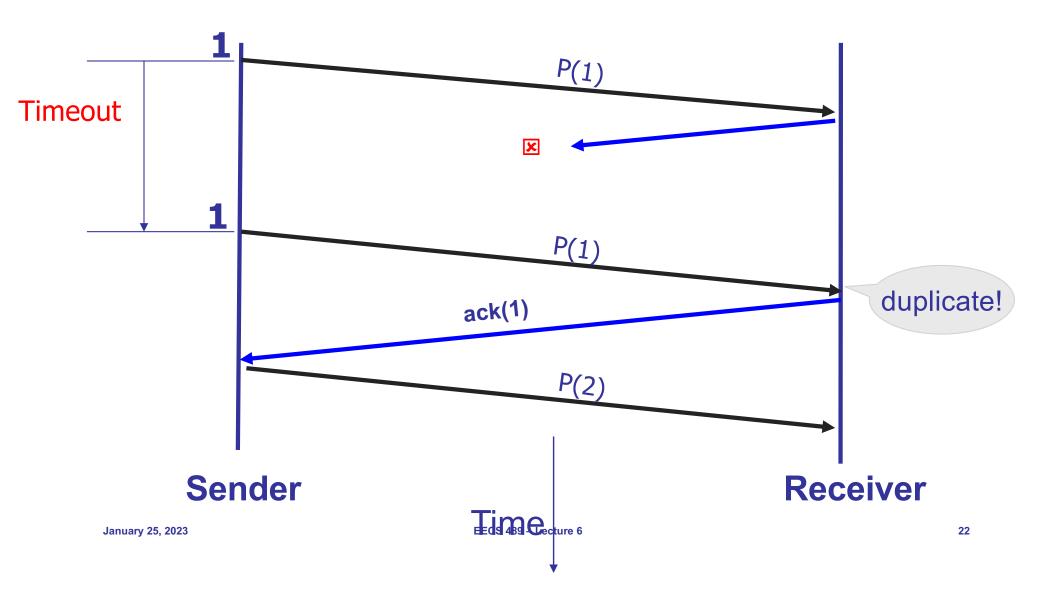

Dealing with packet loss

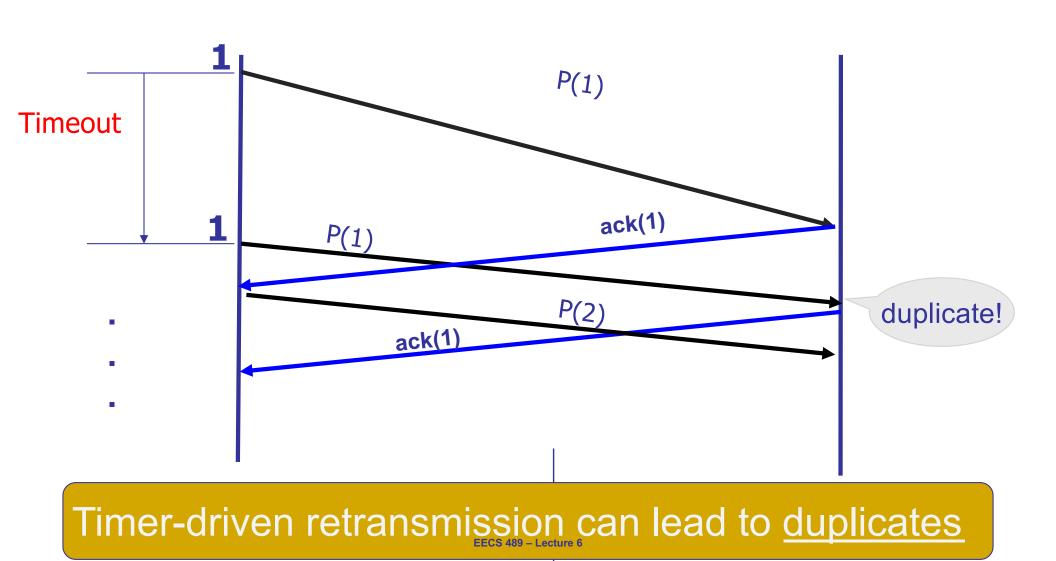

Timer-driven loss detection

Set timer when packet is sent; retransmit on timeout

Dealing with packet loss (of ack)

Dealing with delay

Components of a solution

- Checksums (to detect bit errors)
- Timers (to detect loss)
- Acknowledgements (positive or negative)
- Sequence numbers (to deal with duplicates)

5-MINUTE BREAK!

DESIGNING A RELIABLE TRANSPORT

A Solution: "Stop and Wait"

@Sender

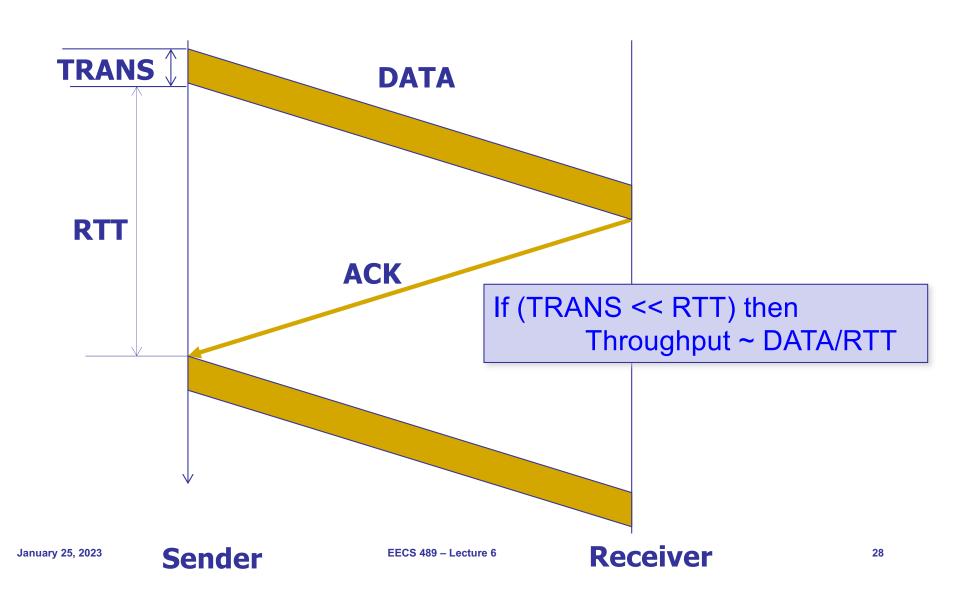

- Send packet(I); (re)set timer;
 wait for ack
- If (ACK)
 - I++; repeat
- If (NACK or TIMEOUT)
 - repeat

@Receiver

- Wait for packet
- If packet is OK, send ACK
- Else, send NACK
- Repeat

 A correct reliable transport protocol, but an extremely inefficient one

Stop & Wait is inefficient

Orders of magnitude

- Transmission time for 10Gbps link:
 - > ~ microsecond for 1500 byte packet
- RTT:
 - > 1,000 kilometers ~ O(10) milliseconds

Three design decisions

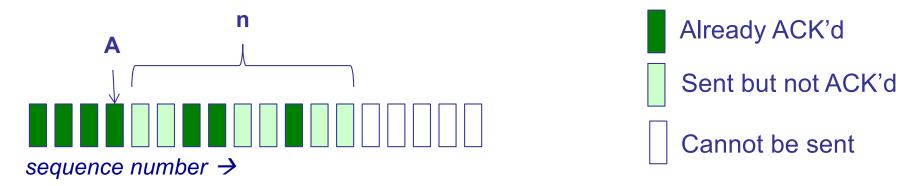

- Which packets can sender send?
- How does receiver ack packets?
- Which packets does sender resend?

Sliding window

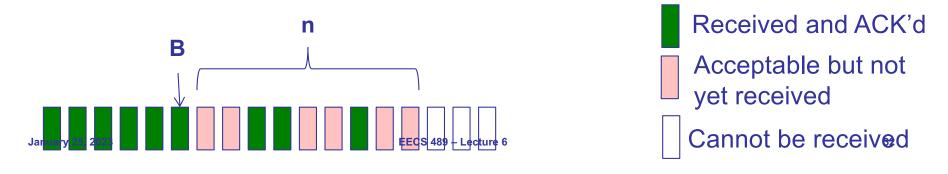

- Window = set of adjacent sequence numbers
 - The size of the set is the window size; assume window size is n
- General idea: send up to n packets at a time
 - Sender can send packets in its window
 - Receiver can accept packets in its window
 - Window of acceptable packets "slides" on successful reception/acknowledgement
 - Window contains all packets that might still be in transit
- Sliding window often called "packets in flight"

Sliding window

Let A be the last ack'd packet of sender without gap;
 then window of sender = {A+1, A+2, ..., A+n}

 Let B be the last received packet without gap by receiver, then window of receiver = {B+1,..., B+n}

Throughput of sliding window

- If window size is n, then throughput is roughly
 - MIN(n*DATA/RTT, Link Bandwidth)
- Compare to Stop and Wait: Data/RTT

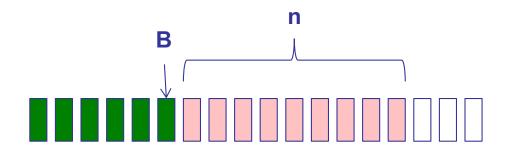

• What happens when n gets too large?

Acknowledgements w/ sliding window

- Two common options
 - Cumulative ACKs: ACK carries next in-order sequence number that the receiver expects

Cumulative acknowledgements

At receiver

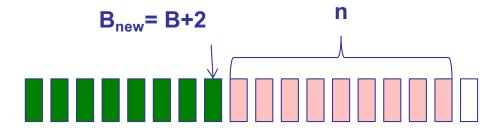

Received and ACK'd

Acceptable but not yet received

Cannot be received

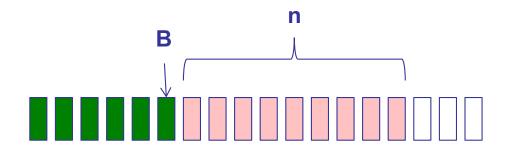

After receiving B+1, B+2

• Receiver sends ACK(B+3) = ACK(B_{new}+1)

Cumulative acknowledgements (cont'd)

At receiver

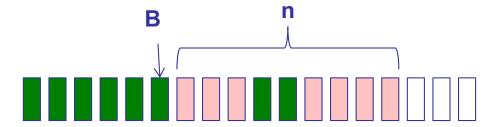

Received and ACK'd

Acceptable but not yet received

Cannot be received

After receiving B+4, B+5

• Receiver sends ACK(B+1)

Acknowledgements w/ sliding window

- Two common options
 - Cumulative ACKs: ACK carries next in-order sequence number the receiver expects
 - Selective ACKs: ACK individually acknowledges correctly received packets
- Selective ACKs offer more precise information but require more complicated book-keeping

Sliding window protocols

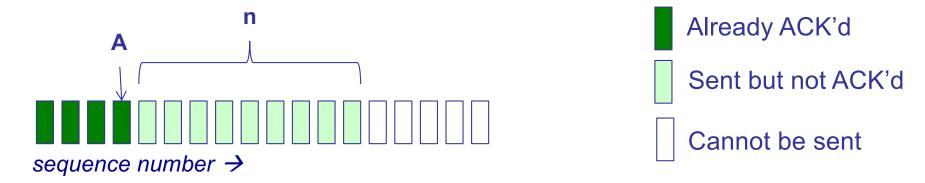

- Resending packets: two canonical approaches
 - Go-Back-N
 - Selective Repeat
- Many variants that differ in implementation details

Go-Back-N (GBN)

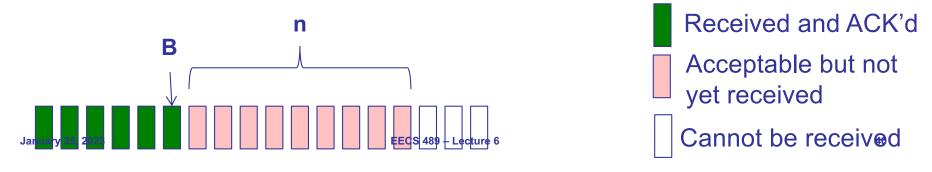

- Sender transmits up to n unacknowledged packets
- Receiver only accepts packets in order
 - Discards out-of-order packets (i.e., packets other than B+1)
- Receiver uses cumulative acknowledgements
 - i.e., sequence# in ACK = next expected in-order sequence#
- Sender sets timer for 1st outstanding ack (A+1)
- If timeout, retransmit A+1, ..., A+n

Sliding window with GBN

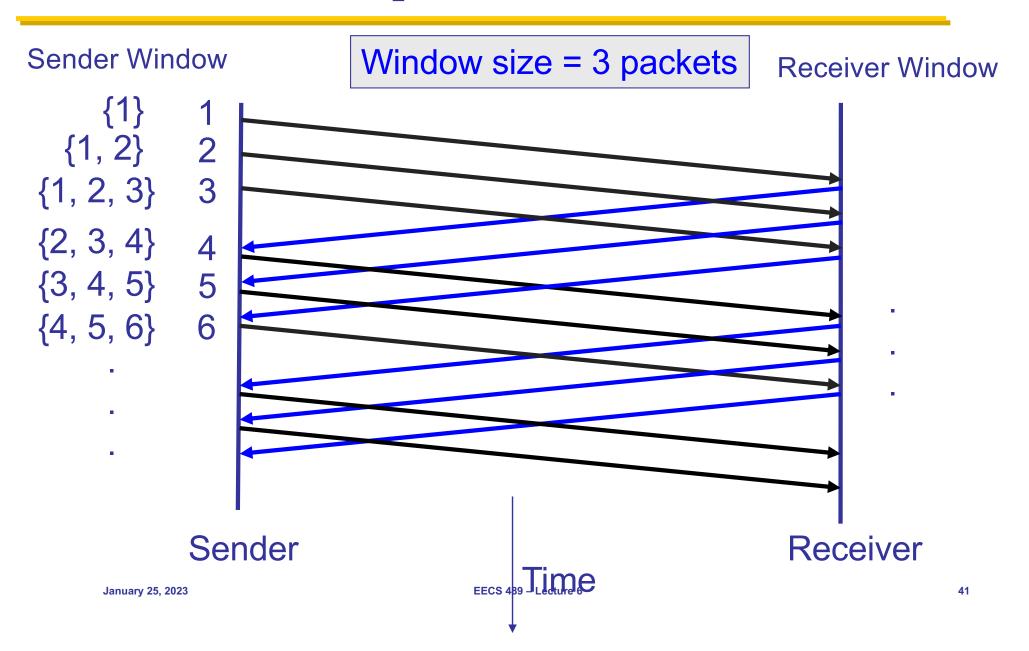

Let A be the last ack'd packet of sender without gap;
 then window of sender = {A+1, A+2, ..., A+n}

 Let B be the last received packet without gap by receiver, then window of receiver = {B+1,..., B+n}

GBN example w/o errors

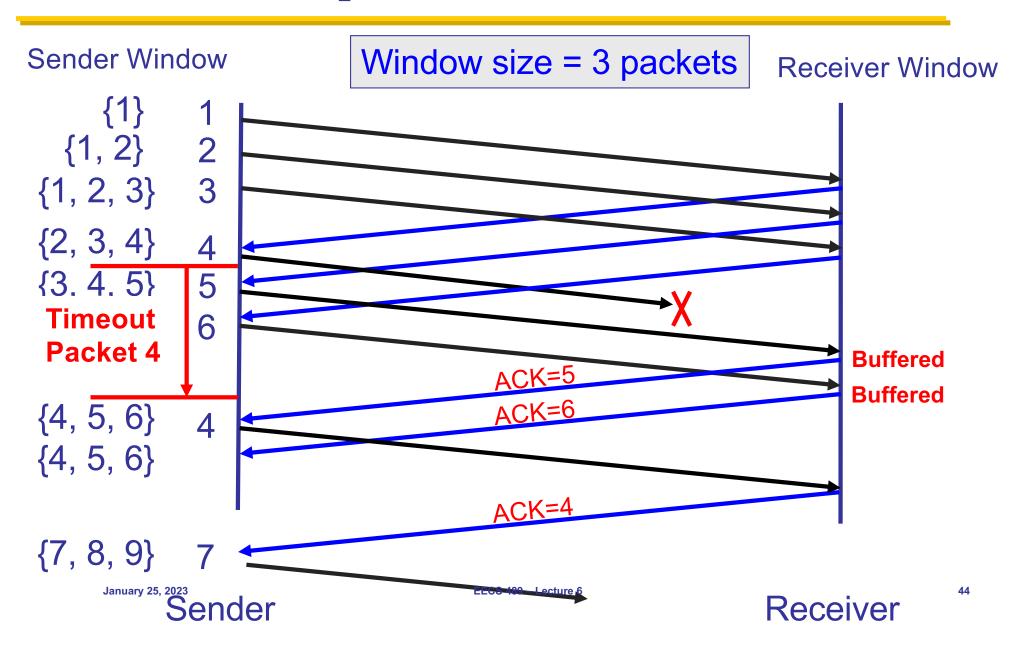

GBN example with errors

Selective Repeat (SR)

- Sender: transmit up to n unacknowledged packets
- Assume packet k is lost, k+1 is not
 - Receiver: indicates packet k+1 correctly received
 - Sender: retransmit only packet k on timeout
- Efficient in retransmissions but complex bookkeeping
 - Need a timer per packet

SR example with errors

GBN vs. Selective Repeat

- When would GBN be better?
 - When error rate is low; wastes bandwidth otherwise
- When would SR be better?
 - When error rate is high; otherwise, too complex

Observations

- For a large-enough window, it is possible to fully utilize a link with sliding windows
- Sender has to buffer all unacknowledged packets, because they may require retransmission
- Receiver may be able to accept out-of-order packets, but only up to its buffer limits
- Implementation complexity depends on protocol details (GBN vs. SR)

Components of a solution

- Checksums (for error detection)
- Timers (for loss detection)
- Acknowledgments
 - Cumulative
 - Selective
- Sequence numbers (duplicates, windows)
- Sliding windows (for efficiency)
- Reliability protocols use the above to decide when and what to retransmit or acknowledge

Summary

- Transport layer allows applications to communicate with each other
- Provides unreliable and reliable mechanisms
- Possible to build reliable transport over unreliable medium
